

# Java Programming Language

## Objectives

- ◆ In this session, you will learn to:
  - ◆ Understand the use of casting objects
  - ◆ Describe overloading methods and methods with variable arguments
  - ◆ Describe overloading constructors and invoking parent class constructors
  - ◆ Understand Wrapper classes
  - ◆ Understand autoboxing of primitive types
  - ◆ Create static variables, methods, and initializers

# Java Programming Language

## Casting Objects

- ◆ Casting objects is used where you have received a reference to a parent class, and you want to access the full functionality of the object of the subclass:
  - ◆ Use `instanceof` to test the type of an object.
  - ◆ Restore full functionality of an object by casting.
  - ◆ Check for proper casting using the following guidelines:
    - ◆ Casts upward in the hierarchy are done implicitly.
    - ◆ Downward casts must be to a subclass and checked by the compiler.
    - ◆ The object type is checked at runtime when runtime errors can occur.

# Java Programming Language

## Methods Using Variable Arguments

- ◆ The `vararg` or variable arguments is a feature provided by J2SE 5.0.
- ◆ It helps to pass variable number of arguments, of the same type, as parameters, to a method.
- ◆ It can be used when you have a number of overloaded methods, which share the same functionality.

# Java Programming Language

## Methods Using Variable Arguments (Contd.)

- ◆ The following example demonstrates the usage of varargs:

```
public class Statistics {  
    public float average(int... nums) {  
        int sum = 0;  
        for ( int x : nums ) {  
            sum += x;  
        }  
        return ((float) sum) / nums.length;  
    }  
}
```

nums is an array  
of type int[]

- ◆ We can invoke the average method by passing any number of arguments as integers.

# Java Programming Language

## Overloading Constructor

- ◆ As with methods, constructors can be overloaded:

- ◆ An example is:

```
public Employee(String name, double  
salary, Date doB)  
public Employee(String name, double salary)  
public Employee(String name, Date DoB)
```

- ◆ Argument lists must differ.
- ◆ You can use the this reference at the first line of a constructor to call another constructor.

# Java Programming Language

## Constructors Are Not Inherited

- ◆ A subclass inherits all methods and variables from the superclass (parent class).
- ◆ A subclass does not inherit the constructor from the superclass.
- ◆ Two ways to include a constructor are:
  - ◆ Use the default constructor
  - ◆ Write one or more explicit constructors

# Java Programming Language

## Invoking Parent Class Constructors

- ◆ To invoke a parent class constructor, you must place a call to `super()` in the first line of the constructor.
- ◆ You can call a specific parent constructor by the arguments that you use in the call to `super()`.
- ◆ If the parent class defines constructors, but does not provide a no-argument constructor, then a compiler error message is issued.

# Java Programming Language

## The Object Class

- ◆ The `Object` class is the root of all classes in Java.
- ◆ A class declaration with no `extends` clause implies `extends Object`. For example:

```
public class Employee  
{  
    ...  
}
```

is equivalent to:

```
public class Employee extends Object  
{  
    ...  
}
```

- ◆ Two important methods of object class are:
  - ◆ `equals()`
  - ◆ `toString()`

# Java Programming Language

## The equals Method

- ◆ The `==` operator determines if two references are identical to each other (that is, refer to the same object).
- ◆ The `equals()` method determines if objects are equal but not necessarily identical.
- ◆ The Object implementation of the `equals()` method uses the `==` operator.
- ◆ User classes can override the `equals` method to implement a domain-specific test for equality.

Note: You should override the `hashCode` method if you override the `equals` method.

# Java Programming Language

## The toString Method

- ◆ The `toString()` method has the following characteristics:
  - ◆ This method converts an object to a `String`.
  - ◆ Use this method during string concatenation.
  - ◆ Override this method to provide information about a user-defined object in readable format.
  - ◆ Use the wrapper class's `toString()` static method to convert primitive types to a `String`.

# Java Programming Language

## Wrapper Classes

- ◆ The Java programming language provides wrapper classes to manipulate primitive data elements as objects.
- ◆ Each Java primitive data type has a corresponding wrapper class in the `java.lang` package.
- ◆ Example of Primitive Boxing using wrapper classes:

```
int pInt = 420;
```

```
Integer wInt = new Integer(pInt);
```

```
// this is called boxing
```

```
int p2 = wInt.intValue();
```

```
// this is called unboxing
```

# Java Programming Language

## Autoboxing of Primitive Types

- ◆ The autoboxing feature enables you to assign and retrieve primitive types without the need of the wrapper classes.
- ◆ Example of Primitive Autoboxing:

```
int pInt = 420;  
Integer wInt = pInt; // this is called autoboxing  
int p2 = wInt;      // this is called autounboxing
```
- ◆ The J2SE 5.0 compiler will create the wrapper object automatically when assigning a primitive to a variable of the wrapper class type.
- ◆ The compiler will also extract the primitive value when assigning from a wrapper object to a primitive variable.

# Java Programming Language

## The static Keyword

- ◆ The `static` keyword is used as a modifier on variables, methods, and nested classes.
- ◆ The `static` keyword declares the attribute or method is associated with the class as a whole rather than any particular instance of that class.
- ◆ Thus, static members are often called class members, such as `class attributes` or `class methods`.

# Java Programming Language

## The static Keyword (Contd.)

### ◆ Static Attribute:

- ◆ A public static class attribute can be accessed from outside the class without an instance of the class.

### ◆ Static Method:

- ◆ A static method can be invoked without creating the instance of the class.
- ◆ Static methods can not access instance variables.

### ◆ Static Initializers:

- ◆ A class can contain code in a static block that does not exist within a method body.
- ◆ Static block code executes once only, when the class is loaded.
- ◆ Usually, a static block is used to initialize static (class) attributes.

# Java Programming Language

## Summary

- ◆ In this session, you learned that:
  - ◆ Casting objects is used where you have received a reference to a parent class, and you want to access the full functionality of the object of the subclass.
  - ◆ The methods which perform closely related tasks can be given the same name by overloading them.
  - ◆ The `varargs` feature helps us to write a generic code to pass variable number of arguments, of the same type to a method.
  - ◆ The `super` keyword is used to call the constructor of the parent class.
  - ◆ The `object` class is the root of all classes. The two important methods of the object class are `equals()` method and `toString()` method.

# Java Programming Language

## Summary (Contd.)

- ◆ Wrapper classes are used to manipulate primitive data elements as objects. Each Java primitive data type has a corresponding `wrapper` class in the `java.lang` package.
- ◆ Autoboxing feature of J2SE 5.0 enables you to assign and retrieve primitive types without the need of the wrapper classes.
- ◆ The `static` keyword declares members (attributes, methods, and nested classes) that are associated with the class rather than the instances of the class.
